clearly present, in the hypervariable domains of env ~~(cf. fig. 6 g and h)~~. As noted for point mutations, env gene and orf F also appear as more susceptible to that form of genetic variation than the rest of the genome. The degree of conservation of these repeats must be related to their date of occurrence in the analyzed sequences : the more degenerated, the more ancient. A very recent divergence of LAV_{BRU} and HTLV-3 is suggested by the extremely low number of mismatched AA between their homologous proteins. However, one of the LAV_{BRU} repeats (located in the Hyl domain of env, ~~fig. 6-f~~) is not present in HTLV-3, indicating that this generation of tandem repeats is a rapid source of genetic diversity. We have found no traces of such a phenomenon, even when comparing very closely related viruses, such as the Mason-Pfizer monkey virus (hereinafter "MPMV") [Sonigo et al., 1986], and an immunosuppressive simian virus (hereinafter "SRV-1") [Power et al., 1986]. Insertion or deletion of one copy of a direct repeat have been occasionally reported in mutant retroviruses [Shimotohno and Temin, 1981 ; Darlix, 1986], but the extent to which we observe this phenomenon is unprecedented. The molecular basis of these duplications is unclear, but could be the "copy-choice" phenomenon, resulting from the diploidy of the retroviral genome [Varmus and Swanstrom, 1984 ; Clark and Mak, 1983]. During the synthesis of the first-strand of the viral DNA, jumps are known to occur from one RNA molecule to another, especially when a break or a stable secondary structure is present on the template; an inaccurate re-initiation on the other RNA template could result in the generation (or the elimination) of a short direct repeat.

Genetic variability and subsequent antigenic modifications have often been developed by micro-organisms as a means for avoiding the host's immune
